

Supplementary Material for
Spatio-temporal variability of zooplankton standing stock in
eastern Arabian Sea inferred from ADCP backscatter
measurements

Ranjan Kumar Sahu, D. Shankar, P. Amol, S.G. Aparna, D.V. Desai

November 27, 2024

1 The supplementary material consists of a detailed comparison with biomass cli-
2 matology from [Aparna et al., 2022] (henceforth, A22). A brief introductory section
3 about components of seasonal cycle and variabilities followed by overview of analysis
4 tools used to identify the former are presented.

5 **S1. Comparison with biomass and ZSS climatology of A22**

6 It is observed that D215 is shallower at all locations and as a result a lower biomass
7 and ZSS as seen in the climatology of the present study (Fig. S1). The difference in
8 D215 is prominent off Goa; while in the previous climatology the D215 is deeper and
9 lies along D23, in the present climatological data the D215 is shallower and lies ~ 20 –
10 40 m above the D23 during January to April. A relatively lower biomass is present
11 above z215 year round which reflects in overall lower ZSS of Goa and Mumbai. In the
12 present data, the ZSS maximum off Mumbai occurs in March instead of February
13 (A22), due to a lower ZSS value. The second maximum occurs in August and is
14 less pronounced in recent data (Fig. S1 d1, d2). There is dramatic decrease in the
15 minima off Mumbai that occurs in October and ZSS increases rapidly afterwards

16 till February, and the minor peak seen in A22 is not observed off Mumbai. Off
17 Kollam, higher biomass occurs from May to June in A22, and from May to June and
18 September to November in the present study, with a ZSS minima in August. The
19 higher ZSS on either side to this minima is less pronounced in A22. This difference in
20 ZSS is clearly seen in the correlation, which is 0.60 off Kollam, while it is 0.94 and 0.98
21 off Mumbai and Goa, respectively. But the correlation reflects ZSS trend similarity,
22 not magnitude deviation over time. In the present study, chlorophyll biomass peaks
23 across all locations in August, and a minor peak off Mumbai. Off Kollam, revealing
24 a zooplankton-phytoplankton relationship discrepancy consistent with A22 findings.

25 **S2. Seasonal cycle and analysis**

26 The seasonal cycle constitutes of annual and semi-annual cycle, and the variability
27 occurring in their respective period band.

28 **S2.1. Annual, intra-annual variability**

29 The biomass time series can be decomposed into distinct period bands spanning days
30 to months. Among these diel vertical migration is the simplest variation, determining
31 zooplankton biomass at a given depth with higher (lower) biomass at night (day),
32 but it is not part of seasonal cycle and not the focus of our study. On a much longer
33 time scale, annual variability reflects changes over the course of a year often influ-
34 enced by seasonal cycles like monsoons. For example, in the case of phytoplankton,
35 upwelling favored by monsoonal winds can vary from year-to-year, thus determin-
36 ing the biomass for a given year uniquely. Intra-annual variability arises due to the
37 asymmetry between the summer and winter monsoons, the asymmetry leads to the
38 semi-annual cycle along with a band around 120 days in WICC ([[Chaudhuri et al.,](#)
39 [2020, 2021](#)]) specifically at SEAS similar to zooplankton biomass ([subsection 3.3](#)).

Hence, intra-annual variability captures fluctuations that occur between seasons due to the asymmetry, e.g., while both summer and winter monsoons are the growing season for chl-a at NEAS, the strength of bloom varies with season. At a further lower temporal scale, the intraseasonal variability arises due to short-term (few days to 90 days) changes and dominates the zooplankton biomass and currents as discussed in [section 4](#).

S2.2. Wavelet analysis and Lanczos filter

Before we understand wavelet analysis, it is imperative to have knowledge about Fourier analysis which decomposes a time series into sum of cosine and sine functions. The power spectrum of Fourier analysis shows peaks corresponding to period or frequency of a cycle and is meaningful for a cycle with known periodicity, e.g., annual and semi-annual cycle with known periodicity of 365 and 180 days, respectively. However, this technique can obscure the non stationary signals within the seasonal cycle variations of a time series [[Amol et al., 2014](#), [Chaudhuri et al., 2020](#)]. In a real world scenario of oceanography, no cycle is continuous when we consider it's strength and extent of cycle. Wavelet analysis was developed to counter this drawback as it provides a representation of time series in time-frequency domain [[Torrence and Compo, 1998](#)]. It employs wavelets, a localized wave-like functions that can be customized by varying wavelet's scale and position along the time series to identify periodic/stationary and irregular non-stationary patterns and their strength with time. This analysis is routinely used in time series data in the field of oceanography and geophysics, biomedical engineering and signal processing etc.

Wavelet analysis has a crucial role to identify the seasonal cycle of zooplankton biomass and ZSS, and understanding of the method to interpret the wavelet figure is vital. Biomass time series at 40 and 104 m is chosen and decomposed to time (abscissa) vs frequency (ordinate) domain. While the time is linearly progressing, the

66 inverse of frequency is represented as period for ease of understanding in logarithm
 67 scale ([Fig. 6](#)). The horizontal lines from the ordinate represents a specific period,
 68 and the color of wavelet spectra along the line shows intensity and continuity of
 69 cycle corresponding to that period. There is two more things keep in mind, 1) The
 70 cone of influence (CoI), beyond which edge effects (because of finite data) distort
 71 the spectrum; 2) Contours of statistical significance, showing patterns and features
 72 that are unlikely to have occurred by chance [[Torrence and Compo, 1998](#)]. For a
 73 cyclic feature to be labeled as present in time series, it must be within the CoI and
 74 be statistically significant. Say, in ([Fig. 6](#)), at the annual scale (365-days period) off
 75 Mumbai, intensity of wavelet spectra is high, it lies well within CoI, and is statistically
 76 significant. The semi-annual cycle along with bursts in intraseasonal scale is also seen.
 77 However, cross period comparison can't be made beyond a specific period band due
 78 to emphasis of normalisation on wavelet power at higher period [[Maraun and Kurths,](#)
 79 [2004](#)]. And for this need of comparison we move to filtering techniques.

80 The Lanczos filter used is a digital construct that allows/restricts signals within
 81 period of interest [[Duchon, 1979](#)]. It is digital analogous to physical filters used in
 82 biology labs to filter zooplankton within a size range. While the wavelet analysis
 83 gives idea about variation of biomass occurring with time at all period, the Lanczos
 84 filtered data shows variation of biomass within a period band of interest. Hence, the
 85 range, distribution and intensity of a period band could be compared with another
 86 band unlike wavelet analysis where comparison can be made in one point of time
 87 to another at same or nearby period only. In the present context, we have made
 88 comparison between multiple bands as discussed in [section 4](#). Taking the time series
 89 at a single depth of 40 m in all three bands shows that the intraseasonal variability
 90 is dominating and its magnitude increases as we move towards equator ([Fig. 11](#)).

Table 1:

The mean, standard deviation at 40 and 104 m of zooplankton biomass (mg m^{-3}), standard deviation of ZSS (gm m^{-2} , 0–140 m) and chlorophyll (mg m^{-3}) at 7 mooring sites are tabulated along with the standard deviation of components of biomass variability, namely intraseasonal, intra-annual and annual. The standard deviation, 3σ of Chl and ZSS is based on the monthly climatological data while the rest are based on the respective daily data.

	40 m biomass		104 m biomass		decrease with depth (40m – 104m)	standard deviation * 3				
	Mean	Std	Mean	Std		Chl	ZSS	Intraseasonal	Intra-annual	Annual

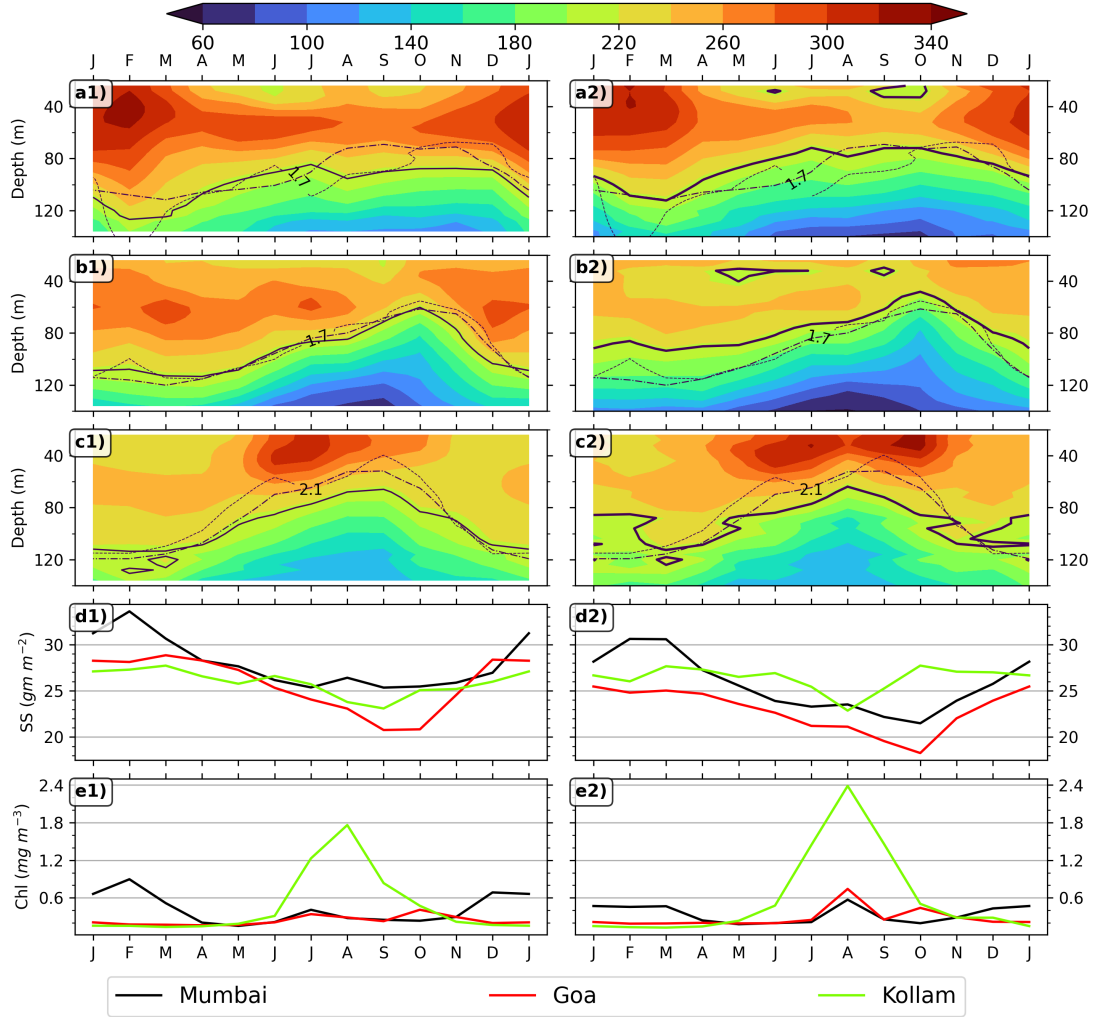

FIGURE S1. Monthly climatology of zooplankton biomass is shown in left panels for 3 locations which were earlier used in [Aparna et al., 2022]; a1, b1 & c1 is the biomass climatology for Mumbai, Goa and Kollam, d1 is for ZSS climatology (24–140 biomass integral), e1 is for chlorophyll biomass climatology; a2, b2, c2, d2 & e2 is same but based on data from 2017 to 2023. The D215 is shown in solid line. The dashed line represents the depth of 23 °C isotherm; oxygen contours are shown in dotted lines and labeled for each location.
